# Bayesian Statistics I

Lecture 2 - Normal and Poisson data. Prior elicitation.

#### Mattias Villani

Department of Statistics Stockholm University

Department of Computer and Information Science Linköping University

### Lecture overview

- The Normal model with known variance
- The Poisson model
- Conjugate priors
- Prior elicitation

## Normal data, known variance - uniform prior

Model

$$x_1, ..., x_n | \theta, \sigma^2 \stackrel{iid}{\sim} N(\theta, \sigma^2).$$

Prior

$$p(\theta) \propto c$$
 (a constant)

Likelihood

$$p(x_1, ..., x_n | \theta, \sigma^2) = \Pi_{i=1}^n (2\pi\sigma^2)^{-1/2} \exp\left[-\frac{1}{2\sigma^2} (x_i - \theta)^2\right]$$

$$\propto \exp\left[-\frac{1}{2(\sigma^2/n)} (\theta - \bar{x})^2\right].$$

Posterior

$$\theta | x_1, ..., x_n \sim N(\bar{x}, \sigma^2/n)$$

## Normal data, known variance - normal prior

Prior

$$\theta \sim N(\mu_0, \tau_0^2)$$

Posterior

$$p(\theta|x_1,...,x_n) \propto p(x_1,...,x_n|\theta,\sigma^2)p(\theta)$$
  
 
$$\propto N(\theta|\mu_n,\tau_n^2),$$

where

$$\frac{1}{\tau_n^2} = \frac{n}{\sigma^2} + \frac{1}{\tau_0^2},$$

$$u_n = w\bar{x} + (1 - w)u_0,$$

and

$$W = \frac{\frac{n}{\sigma^2}}{\frac{n}{\sigma^2} + \frac{1}{\tau_0^2}}.$$

### Normal data, known variance - normal prior

$$\theta \sim N(\mu_0, \tau_0^2) \stackrel{x_1, \dots, x_n}{\Longrightarrow} \theta | x \sim N(\mu_n, \tau_n^2).$$

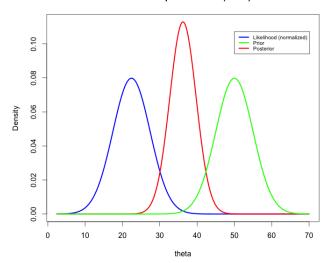

Posterior precision = Data precision + Prior precision

Posterior mean =

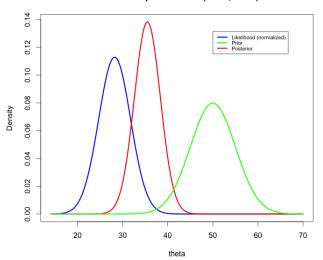

$$\frac{\text{Data precision}}{\text{Posterior precision}} \left( \text{Data mean} \right) + \frac{\text{Prior precision}}{\text{Posterior precision}} \left( \text{Prior mean} \right)$$

- **Data**: x = (22.42, 34.01, 35.04, 38.74, 25.15) Mbit/sec.
- Model:  $X_1, ..., X_5 \sim N(\theta, \sigma^2)$ .
- Assume  $\sigma = 5$  (measurements can vary  $\pm 10$ MBit with 95% probability)
- My prior:  $\theta \sim N(50, 5^2)$ .

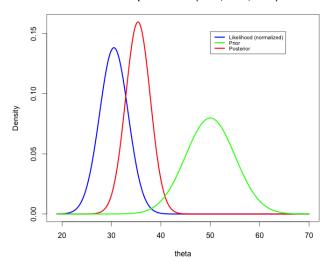

#### Download speed data: x=(22.42)

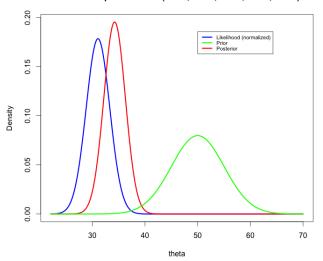

#### Download speed data: x=(22.42, 34.01)

#### Download speed data: x=(22.42, 34.01, 35.04)

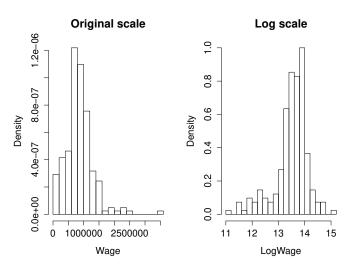

Download speed data: x=(22.42, 34.01, 35.04, 38.74, 25.15)

### Canadian wages data

Data on wages for 205 Canadian workers.

## Canadian wages

Model

$$X_1, ..., X_n | \theta \sim N(\theta, \sigma^2), \ \sigma^2 = 0.4$$

Prior

$$\theta \sim \textit{N}(\mu_0, \tau_0^2),~\mu_0 = 12~\text{and}~\tau_0 = 10$$

Posterior

$$\theta|x_1,...,x_n \sim N(\mu_n,\tau_n^2)$$
,

where  $\mu_n = w\bar{x} + (1 - w)\mu_0$ .

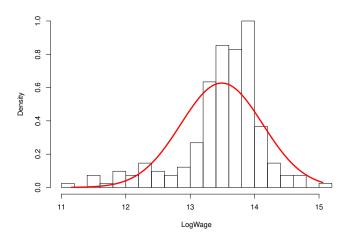

For the Canadian wage data:

$$w = \frac{\sigma^{-2}n}{\sigma^{-2}n + \tau_0^{-2}} = \frac{2.5 \cdot 205}{2.5 \cdot 205 + 1/100} = 0.999.$$

$$\mu_n = w\bar{x} + (1 - w)\mu_0 = 0.999 \cdot 13.489 + (1 - 0.999) \cdot 12 \approx 13.489$$

$$\tau_n^2 = (2.5 \cdot 205 + 1/100)^{-1} = 0.00195$$

# Canadian wages data - model fit

### Poisson model

Model

$$y_1, ..., y_n | \theta \stackrel{iid}{\sim} Pois(\theta)$$

Poisson distribution

$$p(y) = \frac{\theta^y e^{-\theta}}{y!}$$

**Likelihood** from iid Poisson sample  $y = (y_1, ..., y_n)$ 

$$p(y|\theta) = \left[\prod_{i=1}^{n} p(y_i|\theta)\right] \propto \theta^{\left(\sum_{i=1}^{n} y_i\right)} \exp(-\theta n),$$

Prior

$$p(\theta) \propto \theta^{\alpha - 1} \exp(-\theta \beta) \propto Gamma(\alpha, \beta)$$

which contains the info:  $\alpha - 1$  counts in  $\beta$  observations.

### Poisson model, cont.

#### Posterior

$$p(\theta|y_1, ..., y_n) \propto \left[\prod_{i=1}^n p(y_i|\theta)\right] p(\theta)$$

$$\propto \theta^{\sum_{i=1}^n y_i} \exp(-\theta n) \theta^{\alpha-1} \exp(-\theta \beta)$$

$$= \theta^{\alpha + \sum_{i=1}^n y_i - 1} \exp[-\theta (\beta + n)],$$

which is proportional to the  $Gamma(\alpha + \sum_{i=1}^{n} y_i, \beta + n)$  distribution.

### ■ Prior-to-Posterior mapping

Model: 
$$y_1, ..., y_n | \theta \stackrel{iid}{\sim} Pois(\theta)$$
  
Prior:  $\theta \sim Gamma(\alpha, \beta)$ 

Posterior: 
$$\theta|y_1,...,y_n \sim Gamma(\alpha + \sum_{i=1}^n y_i, \beta + n)$$
.

## Example - Number of bids in eBay auctions

#### Data:

- Number of placed bids in n = 1000 eBay coin auctions.
- ▶ Sum of counts:  $\sum_{i=1}^{n} y_i = 3635$ .
- Average number bids per auction:  $\bar{y} = 3635/1000 = 3.635$ .
- **Prior**:  $\alpha = 2$ ,  $\beta = 1/2$ .

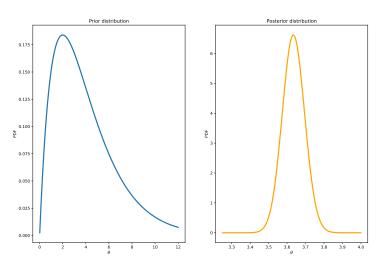

$$E(\theta) = \frac{\alpha}{\beta} = 4$$
  $SD(\theta|\mathbf{y}) = \frac{\alpha}{\beta^2} = 2.823$ 

#### Posterior

$$E(\theta|\mathbf{y}) = \frac{\alpha + \sum_{i=1}^{n} y_i}{\beta + n} = \frac{2 + 3635}{1/2 + 1000} \approx 3.635.$$

$$SD(\theta|\mathbf{y}) = \left(\frac{\alpha + \sum_{i=1}^{n} y_i}{(\beta + n)^2}\right)^{1/2} \approx 0.060.$$

# eBay data - Posterior of $\theta$

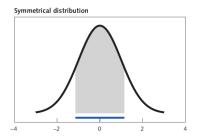

### Posterior intervals

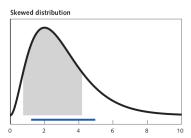

- Bayesian 95% credible interval: the probability that the unknown parameter  $\theta$  lies in the interval is 0.95.
- Approximate 95% credible interval for  $\theta$

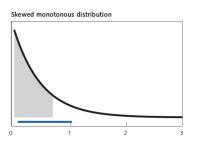

$$E(\theta|y) \pm 1.96 \cdot SD(\theta|y) = [3.517; 3.753]$$

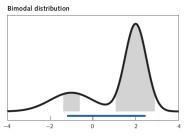

- An exact 95% equal-tail interval is [3.518; 3.754]
- Highest Posterior Density (HPD) interval contains the  $\theta$  values with highest pdf.

# Illustration of different interval types

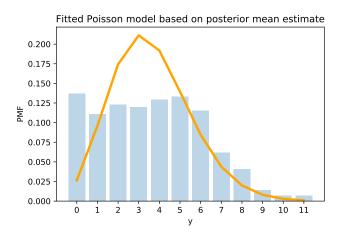

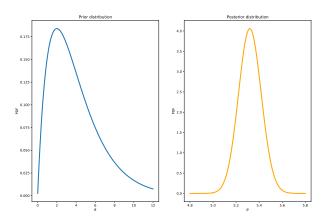

### eBay dat - Fit

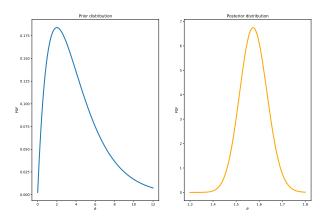

### eBay - low/high seller's reservation price

- The data is very heterogenous. Some auctions start with very high reservations prices (lowest price accepted by the seller).
- Split the data into auctions with low/high reservation prices.
- Low reservation price auctions:
  - ightharpoonup n = 550 eBay coin auctions.
  - Posterior mean: 5.321 bids.
- High reservation price auctions:
  - ightharpoonup n = 450 eBay coin auctions.
  - Posterior mean: 1.576 bids.

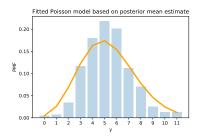

## eBay - low seller's reservation price

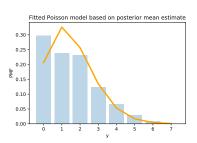

## eBay - high seller's reservation price

### eBay - fit low/high reservation prices

- Better fits, but still not good enough.
- Lab: Fit Poisson regression with reservation price as continuous covariate.

## Conjugate priors

- Normal likelihood: Normal prior→Normal posterior.
- Bernoulli likelihood: Beta prior→Beta posterior.
- Poisson likelihood: Gamma prior→Gamma posterior.
- Conjugate priors: A prior is conjugate to a model if the prior and posterior belong to the same distributional family.
- Formal definition: Let  $\mathcal{F} = \{p(y|\theta), \theta \in \Theta\}$  be a class of sampling distributions. A family of distributions  $\mathcal{P}$  is conjugate for  $\mathcal{F}$  if

$$p(\theta) \in \mathcal{P} \Rightarrow p(\theta|x) \in \mathcal{P}$$

holds for all  $p(y|\theta) \in \mathcal{F}$ .

### **Prior elicitation**

- The prior should be determined (elicited) by an expert. Typically, expert≠statistician.
- Elicit the prior on a quantity that the expert knows well. Convert afterwards.
- Ask probabilistic questions to the expert:
  - $\triangleright$   $E(\theta) = ?$
  - $\triangleright$   $SD(\theta) = ?$
  - $\triangleright$   $Pr(\theta < c) = ?$
  - ▶ Pr(y > c) = ?
- Show some consequences of the elicitated prior to the expert.
- Beware of psychological effects, such as anchoring.

## Prior elicitation - AR(p) example

Autoregressive process or order p

$$y_t = \mu + \phi_1(y_{t-1} - \mu) + ... + \phi_p(y_{t-p} - \mu) + \varepsilon_t, \ \varepsilon_t \stackrel{iid}{\sim} N(0, \sigma^2)$$

- Informative prior on the unconditional mean:  $\mu \sim N(\mu_0, \tau_0^2)$ .
- "Noninformative" prior on  $\sigma^2$ :  $p(\sigma^2) \propto 1/\sigma^2$
- Assume  $\phi_i \sim N(\mu_i, \psi_i)$ , i = 1, ..., p are independent a priori.
- Prior on  $\phi = (\phi_1, ..., \phi_p)$  centered on persistent AR(1) process:  $\mu_1 = 0.8$ ,  $\mu_2 = ... = \mu_p = 0$
- $Var(\phi_i) = rac{c}{i^{\lambda}}$ . "Longer" lags are more likely to be zero a priori.

### Different types of prior information

- Real expert information. Combo of previous studies and experience.
- Vague prior information.
- Reporting priors. Easy to understand the information they contain.
- **Smoothness priors**. Regularization. Shrinkage. Big thing in modern statistics/machine learning.
